

PROJECTIVE SURGERY OBSTRUCTIONS ON CLOSED MANIFOLDS

by

Ian Hambleton<sup>(\*)</sup>

Let  $\pi$  be a finite group and  $f: M^n \rightarrow N^n$  a surgery problem of closed topological  $n$ -manifolds ( $n > 5$ ) with  $\pi_1 N = \pi$  and  $w_1 N = w$ . A basic question is: what elements of  $L_n^h(\pi, w)$  are the surgery obstructions of such problems? If  $C_n^h(\pi, w)$  denotes the subgroup of  $L_n^h(\pi, w)$  generated by these surgery obstructions  $\sigma(f)$ , we can ask for (i) a calculation of  $C_n^h$ , (ii) specific invariants of  $f: M^n \rightarrow N^n$  which detect  $\sigma(f)$  and (iii) specific examples of surgery problems with arbitrary obstruction in  $C_n^h$ .

Wall proved in [W2] that  $\sigma(f)$  is detected by restriction to the 2-Sylow subgroup of  $\pi$  so it is natural to assume that  $\pi$  is a 2-group. Furthermore the calculation of  $L_n^h(\pi, w)$  is still complicated because of  $K_0$  or  $K_1$  difficulties (see [W3] and [HM] for more details). In this paper we answer the analogous questions (i) - (iii) about the image  $\bar{C}_n^h(\pi, w)$  of  $C_n^h$  in  $L_n^P(\pi, w)$ . These groups are the geometric surgery obstruction groups of Maumary [M] or Taylor [T]; algebraically they are  $L$ -groups of quadratic forms on projective (instead of free)  $Z\pi$  modules [R1]. The appropriate version of (ii) is then to ask for invariants detecting  $\sigma(f \times \text{id})$  where  $f \times \text{id}: M \times S^1 \rightarrow N \times S^1$  and the answer to (i) is now possible because the groups  $L^P$  are easier to calculate than  $L^h$ . We give in Section 3 a calculation of  $L_n^P(\pi, w)$  for  $\pi$  a finite 2-group with arbitrary orientation character along the

lines of [HM, ThmA] and define invariants which detect the elements not in  $\bar{C}_n^h(\pi, w)$ .

It has been known [W1, p 176] for some time that part (ii) can be attacked by factoring  $\sigma: [N, G/Top] \rightarrow L_n^h(\pi, w)$  through  $\Omega_n(B\pi \times G/Top)_w$  and using bordism calculations to restrict the images of  $\sigma$ . This was carried out and the image of  $\sigma$  evaluated in  $L^p$  by Morgan and Pardon (unpublished) for  $\pi$  abelian and by Taylor and Williams [TW] for  $\pi$  an arbitrary 2-group (in the orientable case  $w \equiv 1$ ).

Another approach is based on the LN-groups of Wall [W1, 12C], which are obstructions to codimension 1 splitting problems. These groups can be used to define invariants which vanish on closed manifold surgery problems but still detect a large part of the Wall group and some calculations for dihedral and quaternion groups, based on [W3] were carried out in an earlier version of this work (\*). Cappell and Shaneson independently discovered this technique [CS1], [CS2] and exploited it to analyse an interesting surgery problem with obstruction not zero in  $C_1^h(Q8)$  detected by a codimension 3 Arf invariant. This example showed that the list of invariants found by Morgan-Pardon (signature, codim. 0,1,2 Arf) was insufficient in  $L^h$  for  $\pi$  non-abelian.

Our results show that these invariants are in fact sufficient for all 2-groups in  $L^p$ . The higher co-dimension Arf invariants all vanish in  $L^p$  so algebraically they are in the image of  $H^n(\tilde{K}_o(\pi)) \rightarrow L_n^h(\pi)$ . It would be interesting to know the complete list of invariants for  $L^h$ . This has been named the "oozing problem" by John Morgan.

In Section 1 we describe Wall's LN-groups and develop some of their properties. Theorem 3 answers a question in [W1, p. 242]. In

---

\* These results including those of Sections 1,2 in this paper were presented at the Ontario Topology Seminar, October 15, 1977 at the University of Waterloo.

Section 2 the sequences of Section 1 are used to define splitting invariants which generalize those of Browder and Livesay [BL] and the A-invariant described there is recognized as a "twisted" transfer homomorphism (Lemma 5). The calculation of  $L_n^p(\pi, w)$  for  $\pi$  a finite 2-group is given in Section 3 based on the sequence in [HM, Section 1] which relates the  $L^p$  groups to  $L^h$  groups for summands of an involution-invariant maximal order in  $Q\pi$  containing  $Z\pi$ . These in turn are computed by referring to [W3] for  $L^s$  and applying the results of [HM, Section 4] in the  $L^s - L^h$  Rothenberg sequence. These are summarized in Proposition 9, Theorem 10 and Table 1. The LN-groups needed for Section 5 are also calculated in Proposition 11 and Table 2. Our answer to question (iii) on the realization of elements in  $\bar{C}^h$  by specific surgery problems is in Section 4. It is a special case of a construction found with W.-C. Hsiang. In Section 5 we apply the  $L^p$  and LN results to prove that the cup product on  $H^1(\pi; Z/2)$  and the A, B invariants detect all elements of  $L_n^p(\pi, w)$  not in  $\bar{C}_n^h(\pi, w)$  when  $\pi$  is a special 2-group (i.e. cyclic, dihedral, semidihedral or quaternion). The computation of  $\bar{C}_n^h$  for these groups  $\pi$  is in Propositions 12-16. Finally in Section 6 we prove our main result, Theorem 17, answering questions (i)-(iii) in  $L^p$  for a general 2-group.

While working on these questions I have had many stimulating and helpful conversations with Wu-Chung Hsiang, Ib Madsen, Jim Milgram, Bob Oliver, Larry Taylor and Bruce Williams. I also appreciated very much the hospitality of the University of Geneva where I lectured on these results during the Spring of 1980.

### 1. Obstructions to Codimension One Splitting

First we recall the LN-groups of Wall. Let  $\rho \subset \pi$  be an inclusion of groups where  $\rho$  is of index 2 and  $X \xrightarrow{p} Y$  a universal 2-fold cover inducing  $\rho \rightarrow \pi$ . Let  $Z$  be a  $K(\rho, 1)$  meeting the mapping cylinder  $M_Y$  of  $p$  in  $X$  and write  $K(\rho \rightarrow \pi)$  for the triad  $(M_Y \cup Z; Z, X)$ . Wall then considers a cobordism group of objects consisting of: a finite Poincaré pair  $(N^n, M)$  and a manifold pair  $(W^{n+1}, V)$ , a finite Poincaré embedding  $(N, M) \rightarrow (W, V)$  and a smoothing of the embedding  $M \rightarrow V$  together with a map  $(W; N, W - N) \rightarrow K(\rho \rightarrow \pi)$  compatible with  $w(M_Y \cup Z)$ . These cobordism groups are denoted  $LN_n(\rho \rightarrow \pi)$  and Wall proves

Theorem 1 ([W1, 11.6]).

There is a natural exact sequence

$$(1.1) \quad \dots L_{n+1}(\pi) \xrightarrow{j} L_{n+2}(\rho \rightarrow \pi) \rightarrow LN_n(\rho \rightarrow \pi) \rightarrow L_n(\pi) \rightarrow \dots$$

Remarks (i) For  $(\rho \subset \pi) = (1 \subset Z/2)$  the LN-groups were first discovered by Browder-Livesay [BL] and this sequence by Lopez de Medrano [LM],

(ii) In Wall's treatment the  $L^S$  groups are understood,

(iii) If  $\phi: \pi \rightarrow Z/2$  denotes the homomorphism with kernel  $\rho$  and  $w: \pi \rightarrow Z/2$  the orientation character for  $M_Y \cup Z$  the groups  $L_k(\pi)$  have orientation  $w\phi$  while the relative ones  $L_k(\rho \rightarrow \pi)$  have orientation  $w$ ,

(iv) Geometrically the first map  $j$  is obtained by pulling back the orientation line bundle over the surgery problem.

In [W1, 12C] Wall gives implicitly another cobordism description of these LN-groups along the lines of [BL]. Let  $(N_1^n, M_1)$  be a manifold pair with a map to  $Y$  compatible with  $w(Y)$ . Form  $E$ , the pull-back of  $M_Y$  over  $N_1$  and let  $\partial E = \partial_0 E \cup \partial_1 E$  where  $\partial_1 E$  is the pull-back over  $M_1$ .

The objects in the new cobordism group will be manifold pairs  $(W^{n+1}, V)$  together with a homotopy equivalence

$$h: (W, V) \rightarrow (E, \partial_1 E)$$

such that  $h$  is transverse regular on  $M_1 \subset \partial_1 E$  and the induced map  $\partial_1 h: M = h^{-1}(M_1) \rightarrow M_1$  is a homotopy equivalence. The resulting cobordism group is again  $LN_n(\rho \rightarrow \pi)$ . This involves the appropriate version of Wall's  $\pi - \pi$  Theorem. In this formulation there are versions for compact smooth, PL on Top manifolds with different assumptions on the torsion of  $h$ . Using the methods of [PR] there is a version for paracompact manifolds modelled on  $N \times R$ . These different versions lead to groups  $LN^S$ ,  $LN^h$  and  $LN^P$ .

The main result of [W1, 12C] is the following expression for the LN-groups in terms of ordinary L-groups. Recall from [W3] that if  $R$  is a ring with involution  $\alpha$  and  $u \in R^\times$  such that  $u^\alpha = u^{-1}$  and  $x^{\alpha\alpha} = uxu^{-1}$  for all  $x \in R$ , there are Wall groups  $L_n(R, \alpha, u)$ .

Theorem 2  $LN_n(\rho \rightarrow \pi, w) \cong L_n(Z\rho, \alpha, -w(t)g_0^{-1})$  where  $t \in \pi$  generates  $\pi/\rho$ ,  $t^2 = g_0 \in \rho$  and  $x^\alpha = w(x)t^{-1}x^{-1}t$  for all  $x \in \rho$ .

### Remarks

- (i) In [W1] this was proved under the assumption that  $t$  is central of order 2. Similar techniques suffice for the general case.
- (ii) The result hold for  $LN^S$ ,  $LN^h$  or  $LN^P$  (see also [R3]). Our first result is

Theorem 3 There is a natural isomorphism of the exact sequence of Theorem 1 with the sequence:

$$(1.2) \dots L_{n+1}(Z\rho \rightarrow Z\pi, \alpha, u) \rightarrow L_n(Z\rho, \alpha, u) \rightarrow L_n(Z\pi, \alpha, u) \dots$$

where  $u = (-1)w(t)g_0^{-1}$  as above. The isomorphism for the middle term is that of Th. 2 and for the last term "scaling by  $t$ ".

Proof (Sketch). One approach is to follow the spectrum method of Quinn [Q] and Ranicki [R2]. Let  $\underline{L}(Z\pi, w\phi)$  denote the simplicial monoid with  $n$ -simplices of algebraic Poincaré  $(n + 2)$ -ads over  $(Z\pi, w\phi)$ . Similarly let  $\underline{LN}(\rho \rightarrow \pi, w)$  be a simplicial set of algebraic codimension 1 splitting problems. Then Wall's chapter 12C can be interpreted to give the left vertical arrow in a diagram:

$$\begin{array}{ccc} \underline{LN}(\rho \rightarrow \pi, w) & \rightarrow & \underline{L}(Z\pi, w\phi) \\ \downarrow & & \downarrow \\ \underline{L}(Z\rho, \alpha, u) & \rightarrow & \underline{L}(Z\pi, \alpha, u) \end{array}$$

The right vertical map is scaling and both induce isomorphisms on homotopy groups. The long exact sequences of homotopy groups are the two sequences (1.1) and (1.2).

## 2. The A, B, Invariants

We define two invariants for splitting problems. First consider the homomorphism (where  $\rho = \ker(\phi: \pi \rightarrow Z/2)$ )

$$A: L_n(\pi, w) \rightarrow LN_{n-2}(\rho \rightarrow \pi)$$

defined by the composition of  $L_n(\pi, w) \rightarrow L_n(\rho \rightarrow \pi)$  and the map  $L_n(\rho \rightarrow \pi) \rightarrow LN_{n-2}(\rho \rightarrow \pi)$  from Theorem 1.

This homomorphism can be given a more geometrical definition by choosing a manifold  $X^{n-1}$  with  $\pi_1 X = \pi$  and  $w_1 X = w$  and considering the action of  $x \in L_n(\pi, w)$  on the base point  $\text{id}: X \rightarrow X$  in  $S(X)$  via the Wall realization theorem [W1]. This produces a new element  $f: M^{n-1} \rightarrow X$  in

$S(X)$  and so a splitting problem relative to any  $\rho \subset \pi$  of index 2.  $A(x)$  is just the cobordism class of this splitting problem in  $LN_{n-2}(\rho \rightarrow \pi)$ .

In the case  $n \equiv 0(4)$ ,  $(\rho \subset \pi) = (1 \subset \mathbb{Z}/2)$  and  $w \equiv 1$ , this is the  $\alpha$ -invariant of Atiyah-Singer. From the geometrical definition it follows that  $A(x) = 0$  if  $x$  acts trivially on  $S(X^{n-1})$  for some compact Top manifold  $X$  as above. The subgroup of  $L_n^h(\pi, w)$  generated by all such  $x$  is called the inertia subgroup  $I_n^h(\pi, w)$  so we have  $I_n^h(\pi, w) \subset \ker A(\rho \rightarrow \pi)$  for any subgroup  $\rho \subset \pi$  of index 2. Since  $I_n^h(\pi, w) \subset C_n^h(\pi, w)$ , the subgroup of  $L_n^h(\pi, w)$  generated by closed manifold surgery problems, and  $A(x) = 0$  for  $x \in C_n^h(\pi, w)$  also, the  $A$ -invariant can be used to estimate the size of  $C_n^h(\pi, w)$ . Our results in Section 6 will show that the images of  $I_n^h(\pi, w)$  and  $C_n^h(\pi, w)$  in  $L_n^p(\pi, w)$  are equal for  $\pi$  a finite 2-group.

Question: Are  $I_n^h(\pi, w)$  and  $C_n^h(\pi, w)$  always equal for any finite group  $\pi$ ?

To define the next invariant we let  $A_n(\rho \rightarrow \pi) = \ker A$  and choose a (possibly different) subgroup  $\rho' \subset \pi$  of index 2. Define

$$B: A_n(\rho \rightarrow \pi) \rightarrow \overline{LN}_{n-3}(\rho' \rightarrow \pi, w\phi)$$

as follows: if  $x \in A_n(\rho \rightarrow \pi)$  choose  $y \in L_n(\pi, w\phi)$  mapping to  $x$  in sequence (1.1) and consider  $A(y) \in \overline{LN}_{n-3}(\rho' \rightarrow \pi, w\phi)$ . The indeterminacy in  $A(y)$  is the image of the composite

$$\begin{array}{c} \gamma: \text{LN}_{n-1}(\rho \rightarrow \pi, w) \rightarrow \text{L}_{n-1}(\pi, w\phi) \\ \downarrow \\ \text{L}_{n-1}(\rho' \rightarrow \pi, w\phi) \rightarrow \text{LN}_{n-3}(\rho' \rightarrow \pi, w\phi). \end{array}$$

where the horizontal maps come from two sequences of type (1.1). We define  $\overline{\text{LN}}_{n-3}(\rho' \rightarrow \pi, w\phi)$  to be the quotient by  $\text{Im } \gamma$  and let  $B(x) = A(y)$ .

If  $x \in I_n^h(\pi, w)$  then  $A(x) = 0$  and  $B(x) = 0$ . We can identify the composite  $\gamma$  algebraically (Lemma 6) when  $\rho' = \rho$  by considering a functor  $\phi: \underline{\underline{Q}}(Z\rho, \alpha, u) \rightarrow \underline{\underline{Q}}(Z\rho, \alpha, u)$  where  $\alpha, u$  are as in Theorem 2 and  $\underline{\underline{Q}}(Z\rho, \alpha, u)$  is the category of quadratic forms over  $(Z\rho, \alpha, u)$  on free (or projective) modules [W3]. If  $(M, f)$  represents a quadratic form then  $\phi(M, f)$  is represented by the module  $M \quad t((m \otimes t) \cdot x = m(txt^{-1}) \otimes t)$  and form  $\bar{f}(m \otimes t, n \otimes t) = t^{-1}f(m, n)t$ . This induces a homomorphism

$$\phi: \text{L}_n(Z\rho, \alpha, u) \rightarrow \text{L}_n(Z\rho, \alpha, u)$$

Lemma 4. The composite

$$\text{L}_n(Z\rho, \alpha, u) \xrightarrow{i_*} \text{L}_n(Z\pi, \alpha, u) \xrightarrow{i^*} \text{L}_n(Z\rho, \alpha, u)$$

is  $1 + \phi$ , where  $i_*$  is the inclusion map and  $i^*$  the restriction.

The map  $A$  can be identified as just the transfer of the twisted anti-structures.

Lemma 5. The composite

$$L_n(\pi, w) \xrightarrow{S_*} L_n(Z\pi, \alpha, w(t)g_0^{-1}) \xrightarrow{i_*} L_n(Z\rho, \alpha, w(t)g_0^{-1})$$

is the map A where  $S_*$  is induced by "scaling by t" under the identification

$$L_n(Z\rho, \alpha, w(t)g_0^{-1}) \cong LN_{n-2}(\rho \rightarrow \pi, w) \text{ of Th. 2.}$$

Proof: From Theorem 3 we have a commutative diagrams ( $u = w(t)g_0^{-1}$ )

$$(2.1) \quad \begin{array}{ccc} L_n(\pi, w) & \xrightarrow[S_*]{} & L_n(\pi, \alpha', u) \\ \downarrow & & \downarrow j_* \\ L_n(\rho \rightarrow \pi, w) & \xrightarrow[\cong]{} & L_{n+1}(\rho \rightarrow \pi, \alpha, u) \\ \downarrow & & \downarrow \partial_* \\ LN_{n-2}(\rho \rightarrow \pi, w) & \xrightarrow[\cong]{} & L_n(Z\rho, \alpha, u) \end{array}$$

where  $\alpha'(x) = w(x)t^{-1}x^{-1}t$  for  $x \in \pi$  differs from  $\alpha(x) = \phi(x)w(x)t^{-1}x^{-1}t$  on elements of  $\pi - \rho$ . The map  $j_*$  is analogous to that of (1.1) and the composite  $\partial_* j_* = i_*$ . We have used the identification  $L_i(R, \alpha, u) = L_{i+2}(R, \alpha, -u)$  given in [W3].

As a consequence of (2.1) in the proof of Lemma 5:

Lemma 6.

The diagram

$$\begin{array}{ccc} LN_{n-1}(\rho \rightarrow \pi, w) & \xrightarrow{\gamma} & LN_{n-3}(\rho \rightarrow \pi, w\phi) \\ \parallel & & \parallel \\ L_{n-1}(\rho, \alpha, -w(t)g_0^{-1}) & \xrightarrow{1+\phi} & L_{n-1}(\rho, \alpha, -w(t)g_0^{-1}) \end{array}$$

commutes, where the vertical isomorphisms are from Th. 2.

### 3. Calculation of $L^P(\pi, \omega)$

In this section we adapt the method described in [HM, Section 1] to compute  $L_n^P(\pi, \omega)$  for  $\pi$  a finite 2-group and  $\omega: \pi \rightarrow Z/2$  an arbitrary orientation character. The first step is to identify the types of simple involuted algebras in  $Q\pi$  corresponding to the absolutely irreducible characters  $\chi$  of  $\pi$ . If  $\chi$  is not  $Q(\chi)$ -primitive then there is a proper subgroup  $\rho < \pi$  and a character  $\xi$  of  $\rho$  such that  $\xi^* = \chi$ ,  $Q(\xi) = Q(\chi)$  and  $\xi$  is  $Q(\chi)$ -primitive [F]. If  $D(\chi)$ , the summand of  $Q\pi$  containing  $\chi$ , is involution invariant then we can distinguish two cases:

- (i) when  $D(\xi)$  is involution invariant also (in  $Q\rho$ ) or
- (ii) when distinct summands  $D(\xi)$  and  $D(\xi^t)$ ,  $t \notin \rho$  are permuted by the involution. In case (i)  $\ker \xi < \ker \omega$  so that it suffices to consider the summands of  $Q(\rho/\ker \xi)$ , or equivalently to determine the summands of  $Q\pi$  for special 2-groups (cyclic, dihedral, semi-dihedral, quaternion) with arbitrary orientation character. Otherwise if case (ii) applies whenever  $\chi$  is induced by  $\xi$  as above we say that  $\chi$  is  $\omega$ - $Q(\chi)$ -primitive.

The following eight types  $(D, \tau)$  must be distinguished to fully describe the summands in  $Q\pi$  where  $D$  is a simple involuted algebra,  $\tau$  the (anti-) involution on  $D$  and  $\zeta$  denotes a primitive  $2^k$ -th root of 1.

- (3.1)
- 0a:  $Q(\zeta + \bar{\zeta}), \zeta^\tau = \bar{\zeta} \quad (k=1)$
  - 0b:  $Q(\zeta - \bar{\zeta}), \zeta^\tau = -\bar{\zeta} \quad (k>3)$
  - 0c:  $Q(i), i^\tau = i$
  - Ua:  $Q(\zeta), \zeta^\tau = \bar{\zeta}$
  - Ub:  $Q(\zeta), \zeta^\tau = -\bar{\zeta} \quad (k>3)$
  - Uc:  $Q(\zeta + \bar{\zeta}), \zeta^\tau = -\bar{\zeta} \quad (k>3)$

- Ud:  $Q(\zeta - \bar{\zeta}), \zeta^\tau = -\bar{\zeta} \quad (k \geq 3)$
- Ue:  $\Gamma_k = \left( \frac{-1, -1}{Q(\zeta + \bar{\zeta})} \right), \zeta^\tau = -\bar{\zeta} \quad (k \geq 3)$  and  $e_1^\tau = -e_1, e_2^\tau = -e_2$  where  $\{1, e_1, e_2, e_1 e_2\}$  is the usual basis of  $\Gamma_k$  over its centre  $Q(\zeta + \bar{\zeta})$ .
- Sp:  $\Gamma_k, \zeta^\tau = \bar{\zeta} \quad (k \geq 2)$  and  $e_1^\tau = -e_1, e_2^\tau = -e_2$ .
- GL:  $D$  is the sum of two simple algebras interchanged by the involution.

Now the result corresponding to [HM, 1.3] is

Theorem 7. Let  $\pi$  be a finite 2-group and  $w: \pi \rightarrow Z/2$  an orientation character. Under the involution induced on  $Q\pi$  by  $x \rightarrow w(x)x^{-1}$  ( $x \in \pi$ ), the involution-invariant indecomposable summands of  $Q\pi$  are either type GL or isomorphic to one of:

- (1)  $M_\ell(D)$  with involution  $A \rightarrow X A^\tau X^{-1}$  for some  $X \in M_\ell(D)$ , where  $A^\tau$  is  $\tau$ -conjugate transpose,  $X^\tau = \lambda X$  for  $\lambda = \pm 1$ , and  $(D, \tau)$  is in (3.1).
- (2)  $M_\ell(D)$  with involution as in (1) and  $D = D(\xi)$  for some  $w$ - $Q(\xi)$ -primitive character of a subgroup  $\rho \subset \pi$ .

As in the orientable case, it follows that there exists an involution-invariant maximal order  $\mathcal{M} \subset Q\pi$  containing  $Z\pi$  which splits as  $\mathcal{M} = \prod_{\nu} \mathcal{M}_{\nu}$  where  $\mathcal{M}_{\nu}$  is a maximal order in an involution-invariant summand of  $Q\pi$ . A list of the types occurring for primitive characters can be made from (3.1) replacing  $Q$  by  $Z$  except for Ue, Sp where a maximal order in  $\Gamma_k$  must be chosen. Our method of calculation will rely on the sequence [HM, 1.4]:

$$(3.2) \quad \dots \rightarrow L_{n+1}^h(\hat{\mathcal{M}}_2) \rightarrow L_n^p(Z\pi) \rightarrow L_n^h(\hat{Z}_2\pi) \oplus L_n^h(\mathcal{M}) \rightarrow L_n^h(\hat{\mathcal{M}}_2) \rightarrow \dots$$

so we need (by Theorem 7) to compute  $L^h$ -groups for the anti-structures  $(\mathcal{N}, \tau, \pm 1)$  where  $\mathcal{N}$  is Morita equivalent to a simple summand of  $\mathcal{M}$  and  $\tau$  the involution. For the summands corresponding to  $Q(\chi)$ -primitive characters  $\chi$  of  $\pi$ , this is done by using the results of [W3] together with calculations of  $H^*(K_1(\mathcal{N}))$  from [HM, Section 4] to find  $L^h$  through the  $L^s$ - $L^h$  Rothenberg sequence. For the remaining summands we need some further properties of the A,B-invariants. Let  $(\mathcal{M}, \alpha, u)$  denote an anti-structure on the maximal order  $\mathcal{M}$ , induced by an anti-structure  $(Z\pi, \alpha, u)$ , so that

$$(\mathcal{M}, \alpha, u) = \coprod_{\nu} (\mathcal{M}_{\nu}, \alpha_{\nu}, u_{\nu}).$$

Proposition 8.

(1) There is a commutative diagram of exact sequences:

$$\begin{array}{ccccccc} \dots \rightarrow & L_{i+1}^h(\hat{\mathcal{M}}_2) & \rightarrow & L_{i+1}^p(Z\pi \rightarrow \hat{Z}_2\pi) & \rightarrow & L_i^h(\mathcal{M}) & \rightarrow & L_i^h(\hat{\mathcal{M}}_2) \\ & \parallel & & \downarrow & & \downarrow & & \parallel \\ & L_{i+1}^h(\hat{\mathcal{M}}_2) & \rightarrow & L_i^p(Z\pi) & \rightarrow & L_i^h(\hat{Z}_2\pi) \oplus L_i^h(\mathcal{M}) & \rightarrow & L_i^h(\hat{\mathcal{M}}_2) \\ & & & \downarrow & & \downarrow & & \\ & & & L_i^h(\hat{Z}_2\pi) & \cong & L_i^h(\hat{Z}_2\pi) & & \end{array}$$

with the middle horizontal sequence from (3.2).

(2) Let  $Q\pi = \coprod_{\nu} D_{\nu}$  and define

$$\Lambda_i(D_{\nu}, \alpha_{\nu}, u_{\nu}) = L_{i+1}^h(\mathcal{M}_{\nu} \rightarrow (\mathcal{M}_{\nu})_2^{\wedge}, \alpha_{\nu}, u_{\nu})$$

Then there is a natural splitting of the top sequence in (1) and

$$L_{i+1}^P(Z\pi \rightarrow \hat{Z}_2\pi) \cong \prod_{\nu} \Lambda_{i+1}(D_{\nu}, \alpha_{\nu}, u_{\nu}).$$

We now observe that the spectrum argument for Theorem 3 is equally valid for  $\hat{Z}_2\pi$  or the relative groups of  $Z\pi \rightarrow \hat{Z}_2\pi$ . Therefore we have A (and B) invariants defined for these groups also (using a subgroup  $\rho \subset \pi$  of index 2) which are compatible with those of  $Z\pi$ :

$$\begin{array}{ccccc} \rightarrow L_i^P(Z\pi) & \rightarrow & L_i^h(\hat{Z}_2\pi) & \rightarrow & L_i^P(Z\pi \rightarrow \hat{Z}_2\pi) \rightarrow \dots \\ & & \downarrow A & & \downarrow A \\ \rightarrow L_i^P(Z\rho, \alpha, u) & \rightarrow & L_i^h(\hat{Z}_2\rho, \alpha, u) & \rightarrow & L_i^P(Z\rho \rightarrow \hat{Z}_2\rho, \alpha, u) \rightarrow \dots \end{array}$$

is a commutative diagram with  $(Z\rho, \alpha, u)$  the anti-structure of Theorem 2 (Note that  $A = 0$  on  $L_i^h(\hat{Z}_2\pi)$  since  $L_i^h(\hat{Z}_2\rho) \cong L_i^h(\hat{Z}_2\pi)$ .) Again Lemma 5 identifies these maps A as the twisted transfer maps. This interpretation also makes sense on  $L_i^h(\mathcal{M})$  since  $\mathcal{N}$ , a maximal involution-invariant order for  $Z\rho$ , can be chosen so that  $\mathcal{N}$  contains the image of  $\mathcal{M}$  under the usual augmentation  $\varepsilon: Q\pi \rightarrow Q\rho$  where  $\varepsilon(x) = 0$  if  $x \notin \rho$  and then an augmentation map  $\varepsilon: \mathcal{M} \rightarrow \mathcal{N}$  is defined by restriction. If  $h: P \times P \rightarrow \mathcal{M}$  is the form over  $\mathcal{M}$ ,  $\varepsilon \circ h: P \times P \rightarrow \mathcal{N}$  is the restricted form over  $\mathcal{N}$ . From this definition it is clear that if  $\mathcal{M}_{\nu} \subset \mathcal{M}$  corresponds to an absolutely irreducible character  $\chi$  of  $\pi$ , then the image of A restricted to  $L_i^h(\mathcal{M}_{\nu})$  lies in the summands  $L_i^h(\mathcal{N}_{\nu}, \alpha, u)$  corresponding to characters  $\xi$  of  $\rho$  with  $\xi^* = \chi$ . Now we can deal with the summands corresponding to  $w$ - $Q(\chi)$ -primitive characters  $\chi$ .

Proposition 9. Let  $\chi$  be a  $w$ - $Q(\chi)$ -primitive character of  $\pi$  and  $\xi$  a character on  $\rho \subset \pi$  of index 2 with  $\xi^* = \chi$  and  $Q(\xi) = Q(\chi)$ .

(1) The summand  $D(\xi) \subset Q\rho$  corresponding to  $\xi$  is involution-invariant in the twisted anti-structure  $(Q\rho, \alpha, u)$ .

(2) If  $(D(\chi), \tau, 1)$  corresponds to  $\chi$  under the usual anti-structure on  $Q\pi$ , the map  $A$  followed by projection induces an isomorphism

$$A: \Lambda_1^h(D(\chi), \tau, 1) \xrightarrow{\cong} \Lambda_1^h(D(\xi), \alpha, u)$$

From this result we can see that a complete computation of  $L_*^P(Z\pi)$  by our method will depend on calculation of  $LN_*^P(Z\rho \rightarrow Z\pi)$  also. In fact it is enough to give this calculation when  $\rho$  is a special 2-group since then the preceding method (which applies to  $(Z\rho, \alpha, u)$  as well) gives an inductive procedure. Here we will only carry out the last step for  $\rho$  cyclic since this suffices for our application.

First we state the  $L^P$  results.

Theorem 10. Let  $\pi$  be a finite 2-group and  $Q\pi = \prod_{\nu} D_{\nu}$  where  $D_{\nu}$  are indecomposable, involution-invariant algebras. The groups  $\Lambda_*(D_{\nu})$  are zero for  $D_{\nu}$  of type GL but for summands corresponding to the other types (3.1): (here  $\Sigma$  denotes the group of signatures)

(1)  $\Lambda_0(D_{\nu}) = \Sigma$  for  $D_{\nu}$  of type Oa, Ua, Ud or Sp.

(2)  $\Lambda_1(D_{\nu}) = Z/2$  if  $D_{\nu}$  has type Ub, Uc, Ue;

$\Lambda_1(D_{\nu}) = (Z/2)^{2^{n-2}+1}$  if  $D_{\nu}$  has type Sp and centre of degree  $2^{n-2}$  over  $Q$ .

(3)  $\Lambda_2(D_{\nu}) = \Sigma$  if  $D_{\nu}$  has type Ua or Ud;

$\Lambda_2(D_{\nu}) = (Z/2)^{2^{n-2}-1}$  if  $D_{\nu}$  has type Sp and centre of degree  $2^{n-2}$  over  $Q$ .

(4)  $\Lambda_3(D_{\nu}) = Z/2$  if  $D_{\nu}$  has type Oa, Ub, Uc or Ue;

$\Lambda_3(D_\nu)$  is order  $2^{m+2}$  if  $D_\nu$  is type 0b or 0c and centre of degree  $2m$  over  $Q$ .

(5) The map  $L_{2k}^P(Z\pi) \rightarrow L_{2k}^h(\hat{Z}_2\pi) = Z/2$  is onto (and splits) if  $k = 1$ , or if  $k = 0$  and the map  $w: \pi \rightarrow Z/2$  is non-trivial but does not factor through the projection  $Z/4 \rightarrow Z/2$ .

(6) The map  $L_0^h(\hat{Z}_2\pi) \rightarrow L_0^h(Z\pi \rightarrow \hat{Z}_2\pi)$  hits diagonally (a) the elements from characters of degree 1 and type 0a if  $w \equiv 1$  or (b) the elements from  $L_0^h(\hat{M}_2)$  for characters of degree 1 and type 0c if  $w \neq 1$ .

Remark: The fact that  $L_0^P(Z\pi)$  splits whenever it is onto  $L_0^P(\hat{Z}_2\pi)$  follows from the fact that there is a codim 2 Arf invariant problem (Section 4) with obstruction non-zero in  $L_0^P(\hat{Z}_2\pi)$  in that case.

As a corollary to this Theorem we can compute  $L^P$  for special 2-groups (Table 1). Note that when making these calculations the Morita equivalence and scaling needed to reduce  $D_\nu$  to one of the types given may change the unit by  $-1$ . This is denoted by  $0a^-$  for example in the case of the dihedral groups.

In the LN calculation for cyclic 2-groups two new types appear:

$$(3.3) \quad \begin{aligned} \text{Od: } & Q(\zeta), \zeta^\tau = \zeta \quad (k > 3) \\ \text{Uf: } & Q(\zeta), \zeta^\tau = -\zeta \quad (k > 3). \end{aligned}$$

Proposition 11.

Let  $L_{i+1}^P(Z\rho \rightarrow \hat{Z}_2\rho, \alpha, u) = \prod_\nu \Lambda_i(D_\nu, \alpha, u)$  where  $Q\rho = \prod_\nu D_\nu$ . Then for  $D_\nu$  of the type 0d,  $\Lambda_3(D_\nu)$  has order  $2^{m+2}$  when the centre of  $D_\nu$  has degree  $2m$  over  $Q$  and  $\Lambda_i(D_\nu) = 0$  for  $i \neq 3$ ; for  $D_\nu$  of type Uf,  $\Lambda_i(D_\nu) = Z/2$  for  $i = 1, 3$  and zero otherwise.

The LN groups for  $\rho$  cyclic are now given in Table 2. Note that if  $\rho$  is cyclic and type 0a, 0c or 0d is present,  $L_0^h(\hat{Z}_{2\rho}, \alpha, u)$  injects into  $L_0^p(Z\rho + \hat{Z}_{2\rho}, \alpha, u)$  and hits (diagonally) the contribution to the group from  $L_0^h(\hat{M}_2)$  for these summands. Similarly if type 0a<sup>-</sup> is present,  $L_2^h(\hat{Z}_{2\rho}, \alpha, u)$  injects into  $L_2^p(Z\rho + \hat{Z}_{2\rho}, \alpha, u)$ .

#### 4. Codimension k Arf Invariants

Let  $\pi$  be a finite 2-group and  $\rho \subset \pi$  a subgroup of index 2. If  $X^{n-1}$  is a closed PL manifold of dimension  $n-1$  with  $\pi_1 X = \pi$  and  $w = w_1(X)$ , we can construct some elements in  $I_n^h(\pi, w)$  whose surgery obstructions are related to splitting invariants. (This construction is a special case of one which arose in work with Wu-Chung Hsiang). Let  $X \rightarrow B\pi \rightarrow B(\pi/\rho) = BZ/2$  be the composite of the classifying map for  $\pi_1 X$  with the reduction and form

$$f: X \rightarrow \mathbb{R}P^\ell$$

for some  $\ell \gg n$  by simplicial approximation. If  $f$  is made transverse regular to  $\mathbb{R}P^{\ell-k}$  for some  $k > 0$  we obtain  $X_k = f^{-1}(\mathbb{R}P^{\ell-k}) \subset X$ . When the fundamental class  $[X_k]$  of  $X_k$  represents a non-zero class in  $H_{n-k}(X; Z/2)$  let  $k < [n/2]$  and choose an embedded submanifold  $S_k \subset X$  of codimension  $k$  representing the Poincaré dual of  $[X_k]$  under the isomorphism  $H^k(X; Z/2) = \text{HOM}(H_n(X; Z/2), Z/2)$ . Now let  $(E, \partial E)$  denote the disk and sphere bundle of the normal bundle to  $S_k \times (\frac{1}{2})$  in  $X \times I$  and consider  $[E, \partial E; G/TOP, *]$ . Assume  $n-k \equiv 2(4)$  and let  $U_k \in [E, \partial E; G/TOP, *]$  be the THOM class of the normal bundle. This defines a surgery problem (rel  $\partial E$ ) with target  $E$  and so we obtain a normal map

$$F : W^n \rightarrow X \times I$$

which is a homeomorphism on  $\partial_{\pm} W$  by replacing the interior of  $E$  with the surgery problem. The surgery obstruction  $\sigma(F) \in L_n^h(\pi, w)$  for this problem is by definition the "codimension  $k$  Arf invariant". Clearly  $\sigma(F) \in I_n^h(\pi, w)$  and this surgery problem exists only when  $(f^*\alpha)^k \neq 0$  where  $0 \neq \alpha \in H^1(\mathbb{R}P^k; \mathbb{Z}/2)$ .

### 5. Closed Manifold Obstructions for Special 2-Groups

In this section we will use the calculations of Section 3 and the fact that the  $A, B$  invariants of Section 2 vanish on closed manifold obstructions to compute  $\bar{I}_n^h(\pi, w) = \text{Im}(I_n^h(\pi, w) \rightarrow L_n^p(\pi, w))$  for  $\pi$  a special 2-group. It will then be observed that  $\bar{C}_n^h(\pi, w) = \bar{I}_n^h(\pi, w)$  by giving explicit surgery problems for each element. Essentially we show that the  $A, B$  invariants detect the elements not in  $\bar{I}_n^h(\pi, w)$  by calculating the maps in the LN sequences of (1.1). Those in  $\bar{I}_n^h(\pi, w)$  are all detected by the ordinary signature (arising from the map  $L_0(\pi, w) \rightarrow L_0(1) = \mathbb{Z}$  defined when  $w \equiv 1$ ) and Arf invariants in codimensions  $\leq 2$ .

#### (a) $\pi$ cyclic

From Table 1, the torsion in  $L_n^p(\pi, w)$  comes from  $L_n^p(\hat{\mathbb{Z}}_2, \pi)$  or the representation of types  $0a, 0c, Ub$ . For  $\pi = (\mathbb{Z}/2, \pm)$  the answer is well-known: codim.  $0, 1$  Arf invariants ( $w \equiv 1$ ) and codim  $0, 2$  Arf invariants ( $w \not\equiv 1$ ) account for all the torsion. If  $\pi = (\mathbb{Z}/4, +)$  no new classes arise but if  $\pi = (\mathbb{Z}/4, -)$  there is a codim  $1$  Arf invariant (and no codim.  $2$  Arf). Consider the splitting diagram (of sequences (1.1) combined with the usual relative sequences).

$$\begin{array}{ccc}
 & 0 & \\
 & \downarrow & \\
 & L_3^p(Z/4, -) & = & (Z/2)^2 \\
 & \downarrow & & \downarrow
 \end{array}$$

$$LN_2(Z/2 \rightarrow Z/4, -) \rightarrow L_2(Z/4, +) \rightarrow \text{rel} \rightarrow 0$$

$$\begin{array}{ccc}
 \parallel & & \parallel \\
 8Z & \xrightarrow{\quad} & 4Z \oplus Z/2 \\
 & & \downarrow \\
 L_1(Z/4, -) & \rightarrow & L_2(Z/2 \rightarrow Z/4, +) \\
 \parallel & & \\
 0 & & 
 \end{array}$$

This diagram shows that one  $Z/2$  in  $L_3^p(Z/4, -)$  is detected by the codim. 1 Arf invariant while the other has  $A = 0$  but  $B \neq 0$  so does not lie in  $\bar{C}_n^h(\pi, w)$ . For  $(Z/2^n, +)$ ,  $L_3^p(\pi) \xrightarrow{\sim} L_3^p(Z/2)$  by projection so the codim. 1 Arf again detects. If  $\pi = (Z/2^n, -)$ , the part from type 0c is detected by projection  $(Z/2^n, -) \rightarrow (Z/4, -)$  and for the rest consider:

$$\begin{array}{ccc}
 L_1(Z/2^n, -) & = & (Z/2)^t \quad (\text{type Ub}) \\
 & \downarrow & \\
 LN_0 \rightarrow L_0(Z/2^n, +) & \rightarrow & L_1(Z/2^{n-1} \rightarrow Z/2^n, -)
 \end{array}$$

Since  $\text{coker}(LN_0(Z/2^{n-1} \rightarrow Z/2^n, -) \rightarrow L_0(Z/2^n, +))$  is free abelian,  $A \neq 0$  on all of  $L_1(Z/2^n, -)$ . A similar argument works in  $L_3(Z/2^n, -)$  for the type Ub contribution

Proposition 12 For  $\pi = Z/2^n$  and  $\ell \equiv 0, 1, 2, 3 \pmod{4}$ :

$$\bar{C}_\ell(\pi, +) = Z, 0, Z/2, Z/2$$

and

$$\bar{C}_2(\pi, -) = \begin{cases} Z/2, 0, Z/2, 0 & \text{if } n = 1 \\ 0, 0, Z/2, Z/2 & \text{if } n > 2 \end{cases}$$

(b)  $\pi$  dihedral

Here for  $w = (+, +)$  we must consider only  $L_3^p$ . Since  $L_3^p(D2^n) = (Z/2)^{n+1}$  and  $L_3^p(Z/2^{n-1}) = Z/2$  injects:

$$\begin{array}{c} L_3(Z/2^n, -) = Z/2 \\ \downarrow \\ L_3(D2^n) = (Z/2)^{n+1} \\ \downarrow \\ 0 \rightarrow L_2(D2^{n,+}) \rightarrow \text{rel} \\ \parallel \\ Z/2 \oplus \Sigma \end{array}$$

Here  $\Sigma$  denotes the signature part of  $L_2$  and  $\text{rel}$  is the relative group in the vertical sequence. Therefore  $\ker A = (Z/2)^2$  and these are both in  $C_3(D2^n)$ : one from  $C_3(Z/2^{n-1})$  and the other a  $\text{codim. } 1$  Arf.

For  $(D2^n, +-)$ ,  $L_1^p = (Z/2)^{n-2}$  and  $A \neq 0$  on all these. For  $(D2^n, -+)$  we first calculate that

$$L_1^p(Z/2^{n-1}, -) \cong L_1^p(D2^n, -+)$$

so that we take  $\rho = D2^{n-1}$  instead to compute the  $A$ -invariant. Then

$$\begin{array}{c}
 0 \\
 \downarrow \\
 L_1^P(D2^n, -+) = (Z/2)^{n-2} \\
 \downarrow \\
 L_0^P(D2^n, ++) \rightarrow \text{rel} \\
 \parallel \quad \downarrow \\
 \Sigma \\
 L_0^P(D2^{n-1}, ++) = \Sigma'
 \end{array}$$

The transfer map  $L_0^P(D2^n) \rightarrow L_0^P(D2^{n-1})$  is injective on the cokernel of  $LN_0^P(D2^{n-1} \rightarrow D2^n) \rightarrow L_0^P(D2^n)$  so  $A \neq 0$  on all of  $L_1^P(D2^n, -+)$ .

In  $L_3^P(D2^n, -+)$  the type Uc classes are not hit from  $L_3^P(Z/2^{n-1}, -)$  so that since  $L_2^P(D2^n, --) = Z/2$  (hit from  $LN_2(Z/2^{n-1} \rightarrow D2^n)$ ) the A-invariant detects

$$\text{coker } (L_3^P(Z/2^{n-1}, -) \rightarrow L_3^P(D2^n, -+)).$$

Finally the type 0a class is hit from  $L_3^P(Z/2^{n-1}, -)$  so is in  $\bar{C}_3(D2^n, -+)$ .

Proposition 13. For  $\pi = D2^n$  and  $\ell \equiv 0, 1, 2, 3 \pmod{4}$ :

$$\bar{C}_\ell(\pi, ++) = Z, 0, Z/2, (Z/2)^2$$

$$\bar{C}_\ell(\pi, +- ) = Z/2, 0, Z/2, 0$$

$$\bar{C}_\ell(\pi, -+ ) = Z/2, 0, Z/2, Z/2$$

(c)  $\pi$  semi-dihedral

Since the projection  $L_1^P(SD2^n) \rightarrow L_1^P(D2^{n-1})$  detects the torsion classes except from the 0b representation, it suffices to consider these in  $L_3^P(SD2^n, -+)$ . However these elements are not hit from

$L_3^P(SD2^{n-1}, ++)$  and the inclusion map  $L_2(Q2^{n-1}, ++) \rightarrow L_2(SD2^n, ++)$  does not hit the signatures at the Ob representation. Therefore a combination of the A-invariants for  $D2^{n-1} \subset SD2^n$  and  $Q2^{n-1} \subset SD2^n$  (in codimension one) detects these elements. A similar arguments works for  $L_1^P(SD2^n, --)$ .

Proposition 14 The projection map

$$L_i^P(SD2^n, w) \rightarrow L_i^P(D2^{n-1}, w)$$

induces an isomorphism on  $\bar{C}_2$ .

(d)  $\pi$  quaternion

First let  $\pi = Q8$  and  $w \equiv 1$ .

From the diagram:

$$\begin{array}{ccc} & L_3(Z/4) = Z/2 & \\ & \downarrow & \\ & L_3(Q8) = (Z/2)^3 & \\ Z \oplus Z/2 & \downarrow & \\ \parallel & & \\ L_2(Q8, +- ) \rightarrow \text{rel} \rightarrow Z/2 \rightarrow 0 & & \end{array}$$

we see that  $\bar{C}_3(Q8, ++ ) = (Z/2)^2$  and the other generator of  $L_3$  has  $A \neq 0$ .

$$\begin{array}{c}
 0 \\
 \downarrow \\
 L_1(Q8) = (Z/2)^2 \\
 \downarrow \\
 0 \rightarrow L_0(Q8, +- ) \rightarrow \text{rel} \rightarrow Z/2 \\
 \parallel \\
 Z/2
 \end{array}$$

so the A-invariant detects one  $Z/2$  in  $L_1(Q8)$ . The other is detected by the codim 2 Arf invariant in  $L_0(Q8, +-)$  since by projection  $L_0(Q8, +- ) \xrightarrow{\cong} L_0(Z/2, -)$  and the splitting diagram is natural. Since  $\alpha^3 = 0$  for  $\alpha \in H^1(Q8; Z/2)$  the codimension 3 Arf invariant does not exist and  $\bar{C}_1(Q8) = 0$ . Notice that in the Cappell-Shaneson example different index 2 subgroups were used to do the iterated splittings. They exploited the fact that  $\alpha^2 \beta \neq 0$  for  $\alpha, \beta$  generators of  $H^1(Q8; Z/2)$ .

For  $(Q8, -+)$  one  $Z/2$  of  $L_3^P(Q8, -+) = (Z/2)^2$  is in the image of  $\bar{C}_3(Z/4, -)$  and the other is detected by the A-invariant.

Proposition 15 For  $\pi = Q8$  and  $\ell = 0, 1, 2, 3 \pmod{4}$

$$\bar{C}_\ell(\pi, ++ ) = Z, 0, Z/2, (Z/2)^2$$

$$\bar{C}_\ell(\pi, +- ) = Z/2, 0, Z/2, Z/2$$

Next let  $\pi = Q2^n$  for  $n \geq 4$ . Since

$$L_2^P(Z/2^{n-1}) \rightarrow L_2(Q2^n)$$

is onto ( $w \equiv 1$ ) and the torsion-free part of  $L_2^P(Z/2^{n-1})$  can be detected by the A-invariant (modulo the image of  $L_2^P(Z/2^{n-2})$ ),  $\bar{C}_2(Q2^n, ++ ) = Z/2$

detected by the ordinary Arf invariant.

This can be seen considering the Frobenius inclusion

$$Q2^n \subset Z/2^{n-1} \wr Z/2 = (Z/2^{n-1} \times Z/2^{n-1}) \rtimes Z/2$$

into the wreath product. This has the property that if  $\chi$  is the type Sp character on  $Q2^n$  induced from  $\xi$  on  $Z/2^{n-1} \subset Q2^n$  then  $\chi$  extends to  $\tilde{\chi}$  which is induced from  $\xi \times 1$  on  $Z/2^{n-1} \times Z/2^{n-1}$ . Since the translates of  $\xi \times 1$  in the wreath product are distinct the construction at the end of Section 5 eliminates the other elements of  $L_2(Q2^n)$ .

The same argument proves the  $\bar{C}_0(Q2^n, +-)$  =  $Z/2$ . Now in the splitting diagram  $\ker A \subset L_1(Q2^n, ++)$  is detected by  $L_0(Q2^n, +-)$  so  $\bar{C}_1(Q2^n, ++)$  = 0 as for Q8. Similarly, in  $L_3(Q2^n, +-)$  the image of  $L_3(Z/4, -)$  gives one closed manifold class. The remaining elements in  $\ker A$  are detected by  $L_2(Q2^n, ++)$  so  $\bar{C}_3(Q2^n, +-)$  =  $Z/2$ .

For  $(Q2^n, -+)$  the diagram:

$$\begin{array}{c} L_3^p(Q2^{n-1}, ++) \\ \downarrow \\ L_3^p(Q2^n, -+) \\ \downarrow \\ L_2^p(Q2^n, ++) \rightarrow \text{rel} \end{array}$$

and the fact that the Ue class in  $L_3^p(Q2^n, -+)$  is not hit from  $L_3^p(Q2^{n-1}, ++)$  shows that the projection

$$\bar{C}_3(Q2^n, -+) \rightarrow \bar{C}_3(D2^{n-1}, -+)$$

is an isomorphism. A similar argument proves that  $\bar{C}_1(Q2^n, --) = 0$  using the splitting diagram with subgroup  $(Q2^{n-1}, +-)$ .

Proposition 16 Let  $\pi = Q2^n$ ,  $n > 4$  and  $\ell = 0, 1, 2, 3 \pmod{4}$ ,

$$\bar{C}_\ell(Q2^n, ++) = \mathbb{Z}, 0, \mathbb{Z}/2, (\mathbb{Z}/2)^2$$

$$\bar{C}_\ell(Q2^n, +- ) = \mathbb{Z}/2, 0, \mathbb{Z}/2, \mathbb{Z}/2$$

$$\bar{C}_\ell(Q2^n, -+ ) = \mathbb{Z}/2, 0, \mathbb{Z}/2, \mathbb{Z}/2$$

## 6. Closed Manifold Obstructions for Arbitrary 2-Groups

In this section we will give the calculation of  $\bar{C}_\ell(\pi, w)$  for  $\pi$  a finite 2-group in terms of the characters of  $\pi$ .

Theorem 17 Let  $\pi$  be a finite 2-group and  $w: \pi \rightarrow \mathbb{Z}/2$  an orientation character.

$$(1) \quad \text{If } w \equiv 1, \quad \bar{C}_0 = \mathbb{Z}, \quad \bar{C}_1 = 0, \quad \bar{C}_2 = \mathbb{Z}/2 \quad \text{and} \\ \bar{C}_3(\pi) \cong \bar{C}_3(\pi/[\pi, \pi]) \subset H_1(\pi; \mathbb{Z}/2).$$

These are detected by signature, codim 0 Arf, and codim 1 Arf respectively.

$$(2) \quad \text{If } w \neq 1, \quad \bar{C}_0 = \mathbb{Z}/2 \text{ when } w \text{ does not factor through } \mathbb{Z}/4, \text{ otherwise} \\ \bar{C}_0 = 0, \quad \bar{C}_1 = 0, \quad \bar{C}_2 = \mathbb{Z}/2 \quad \text{and} \quad \bar{C}_3 = (\mathbb{Z}/2)^s \text{ where} \\ s < \# \{ \text{summands of } Q\pi \text{ of type } Sp, Oa \text{ and } Oc \}. \text{ These are detected by} \\ \text{the codim 2, codim 0 and codim 1 Arf invariants.}$$

Proof: Let  $f: M^n \rightarrow N^n$  ( $n > 5$ ) represents a surgery problem of closed TOP  $n$ -manifolds with  $\sigma(f) \in L_n^h(\pi, w)$ . The result is first proved in dimension 4 by calculating the possible image of  $[X^4, G/TOP]$  in  $L_4^p(\pi, w)$  so we assume inductively that it is true for dimensions  $< n$ . We let

$a = i_*\sigma(f) \in L_n^P(\pi, w)$  and assume that  $a = (a_\chi) \in \prod_\chi \Lambda_n(D(\chi))$  using the description of  $L^P$  in Proposition 8. This is possible since any contribution to  $i_*\sigma(f)$  from  $L_n(\hat{\mathbb{Z}}_2\pi)$  can be eliminated by taking the sum of this problem with a simply-connected surgery problem or a codim 2 Arf invariant. Furthermore by Proposition 9 we can assume that  $a_\chi = 0$  unless  $\chi$  is induced from a primitive character.

Let  $\chi$  be a character of  $\pi$  for which  $a_\chi \neq 0$  and choose  $\rho \subset \pi$  with a character  $\xi$  such that  $\xi^* = \chi$ ,  $Q(\xi) = Q(\chi)$ ,  $\xi$  is primitive and  $\rho/\ker \xi$  a special 2-group.

Lemma 18 By the inductive assumption (and subtracting off codim  $k$  Arf invariants as before) we can assume that there exists  $b \in L_n^P(\rho, w)$  such that  $b$  has image  $a$  under the map

$$L_n^P(\rho, w) \rightarrow L_n^P(\pi, w).$$

Assuming this we notice that by construction  $b_\xi \neq 0$  hits  $a_\chi$  and  $b_\xi$  is detected by

$$L_n^P(\rho, w) \rightarrow L_n^P(\rho/\ker \xi, w)$$

If  $N = N_1 \cup N_2$  where  $\pi_1 N_1 = \pi$  and  $\pi_1 N_2 = \pi_1(\partial N_2) = \rho$ , we can assume that  $f = f_1 \cup f_2$  where  $f_1 : M_1 = f^{-1}(N_1) \rightarrow N_1$  is a homotopy equivalence and  $f_2 : M_2 = f^{-1}(N_2) \rightarrow N_2$  is a problem over  $\rho$  with obstruction  $b$ . Now define  $\tilde{f}_1 : \tilde{M}_1 \rightarrow \tilde{N}_1$  (the covering with  $\pi_1 = \rho$ ) assuming  $\rho \triangleleft \pi$  and observe that the splitting problem  $\partial \tilde{f}_1 : \partial \tilde{M}_1 \rightarrow \partial \tilde{N}_1$  relative to any index 2 subgroup  $\rho_0 \subset \rho$  vanishes in  $LN_{n-2}(\rho_0 \rightarrow \rho)$  because it is null-bordant using  $(\tilde{M}_1, \tilde{f}_1)$  and the second description

of Section 1 for LN. This splitting problem is also the boundary of  $|\pi:\rho|$  copies of  $f_2 : M_2 \rightarrow N_2$  where the copy corresponding to a coset  $t\rho$  has fundamental group identified as  $t\rho t^{-1} \subset \pi$ . Since  $\rho \triangleleft \pi$  the characters  $\xi^t$  determine distinct summands of  $Q\rho$  and since the A-invariant splits according to the decomposition of  $Q\rho$  (see the discussion following Prop. 8) it follows that  $A(b_\xi) = 0$ . If  $\rho$  is not normal in  $\pi$  we modify the argument by first identifying in pairs (using covering homeomorphisms) those boundary components of  $(\tilde{M}_1, \tilde{f}_1)$  for cosets  $t\rho$  such that  $t\rho t^{-1} \neq \rho$ . Similarly,  $B(b_\xi) = 0$  and by naturality (choosing  $\rho_0 \supset \ker \xi$ ) the same is true for the image of  $b_\xi$  in  $L_n^P(\rho/\ker \xi, w)$ . The calculations of Section 5 now imply the desired description of  $b_\xi$ . Since  $b_\xi$  and hence  $a_\chi$  is represented by a codim  $k$  Arf invariant for  $k \leq 2$  it can be subtracted off and the argument repeated.

Proof of Lemma 18 Consider the splitting diagram:

$$\begin{array}{ccc}
 L_n^P(\rho, w) & & \\
 \downarrow & & \\
 L_n^P(\pi, w) & & A \\
 \downarrow & \searrow & \\
 L_{n-1}^P(\pi, w\phi) \rightarrow L_n^P(\rho \rightarrow \pi, w) \rightarrow LN_{n-2}(\rho \rightarrow \pi, w) & & 
 \end{array}$$

Since  $f : M \rightarrow N$  is a closed manifold problem there exists a normal map  $g : M' \rightarrow N'$  induced from  $f$  by transversality on a characteristic codimension 1 submanifold  $N' \subset N$  corresponding to the subgroup  $\rho \subset \pi$  of index 2 (see Section 4). Then  $i_*\sigma(g) \in L_{n-1}^P(\pi, w\phi)$  hits the image of  $i_*\sigma(f)$  in  $L_n^P(\rho \rightarrow \pi, w)$  and by the inductive assumption  $i_*\sigma(g)$  can be represented as a sum of suitable  $(n-1)$ -dimensional (simply-connected)

signature or codim  $k$  Arf invariant problems for  $k < 2$ .

However the signature problem does not exist in codimension 1 (the complement of a tubular neighbourhood of  $N' \subset N$  provides a null-bordism) and the codim. 0 Arf invariant on  $N'$  gives a codim 1 Arf invariant on  $N$ . The other terms in the sum, codim 1 or 2 Arf invariants, do not give rise to non-zero elements in  $L_n^P(\rho \rightarrow \pi, w)$  even when they exist because they lie in summands of  $L_{n-1}^P(\pi, w\phi)$  detected by representations on subquotients of  $\pi$  of the form  $(\mathbb{Z}/2, \pm)$  or  $\mathbb{Z}/4, -$ ) and the calculations of Section 5 apply.

This argument shows that by adding suitable  $n$ -dimensional closed manifold problems to  $f: M \rightarrow N$  we can assume that the image of  $i_*\sigma(f)$  in  $L_n^P(\rho \rightarrow \pi, w)$  is zero.
