1. What is the fiscal cliff?

[-]

The term “fiscal cliff” is Washington shorthand for a series of automatic spending cuts and tax increases set to take effect in January. If enacted, they would amount to the largest spurt of deficit reduction in more than 40 years but could also push the country back into a recession.

3. What happens if we go over the fiscal cliff?

Analysts have said that going over the fiscal cliff could derail the economy's fragile recovery. The nonpartisan Congressional Budget Office predicts that a recession would be significant but brief, with unemployment peaking around 9 percent and economic growth recovering during the second half of 2013. The International Monetary Fund has estimated that the automatic spending cuts and tax increases would knock perhaps four percentage points of growth off of a U.S. economy that is already only experiencing slow growth. Click on the image at right for a graphic explaining the situation.

In other words: Keynes roolz!

Austerity versus deficit spending: the mathematics of government intervention in macroeconomics

M. R. Grasselli

Introduction

Keen model without government

Persistence theory

Introducing government

Examples

- The strand of DSGE economists associated with RBC theory made the following predictions after 2008:
 - 1 Increases government borrowing would lead to higher interest rates on government debt because of “crowding out”.
 - 2 Increases in the money supply would lead to inflation.
 - 3 Fiscal stimulus has zero effect in a perfect world and negative effect in practice (because of decreased confidence).

Introducing
government

Examples

- The strand of DSGE economists associated with New Keynesianism got all these predictions more or less right.
- Works by augmenting DSGE with ‘imperfections’ (sticky wages, asymmetric information, imperfect competition, frictions in financial markets, ...).
- Still DSGE at core - analogous to adding epicycles to Ptolemaic planetary system.
- For example: “Ignoring the foreign component, or looking at the world as a whole, the overall level of debt makes no difference to aggregate net worth – one person’s liability is another person’s asset.” (Paul Krugman and Gauti B. Eggertsson, 2010, pp. 2-3)

Then we can safely ignore this:

Examples

“We can then model a crisis like the one we now face as the result of a ‘deleveraging shock.’ For *whatever reason*, there is a sudden downward revision of acceptable debt levels a ‘Minsky moment.’ This forces debtors to sharply reduce their spending. If the economy is to avoid a slump, other agents must be induced to spend more, say by a fall in interest rates. But if the deleveraging shock is severe enough, even a zero interest rate may not be low enough. So a large deleveraging shock can easily push the economy into a liquidity trap.” Paul Krugman, *Debt, deleveraging, and the liquidity trap*, 2010. (emphasis added).

Examples

- Stock-flow consistent models emerged in the last decade as a common language for many heterodox schools of thought in economics.
- Consider both real and monetary factors from the start
- Specify the balance sheet and transactions between sectors
- Accommodate a number of behavioural assumptions in a way that is consistent with the underlying accounting structure.
- Reject silly (and mathematically unsound!) hypotheses such as the RARE individual (representative agent with rational expectations).
- See Godley and Lavoie (2007) for the full framework.

An example of a (fairly general) Godley table

Special case: Keen (1995)

- Let $D = L - M_f$ and assume that $p = p_0$, $r_M = r_F = r$.
- Supposing further that $\Phi = \Phi(\lambda)$ and $I = \kappa(\pi)Y$, where $\pi = 1 - \omega - rd$, leads to

$$\dot{\omega} = \omega [\Phi(\lambda) - \alpha]$$

$$\dot{\lambda} = \lambda \left[\frac{\kappa(1 - \omega - rd)}{\nu} - \alpha - \beta - \delta \right] \quad (1)$$

$$\dot{d} = d \left[r - \frac{\kappa(1 - \omega - rd)}{\nu} + \delta \right] + \kappa(1 - \omega - rd) - (1 - \omega)$$

- Observe that the equation for M_h separates as

$$\dot{M}_h = w\ell + r_M M_h - C(\omega, M_h), \quad (2)$$

and only depends on the rest of the system through w .

- The system (1) has a good equilibrium at

$$\bar{w} = 1 - \bar{\pi} - r \frac{\nu(\alpha + \beta + \delta) - \bar{\pi}}{\alpha + \beta}$$

$$\bar{\lambda} = \Phi^{-1}(\alpha)$$

$$\bar{d} = \frac{\nu(\alpha + \beta + \delta) - \bar{\pi}}{\alpha + \beta}$$

with

$$\bar{\pi} = \kappa^{-1}(\nu(\alpha + \beta + \delta)),$$

which is stable for a large range of parameters

- It also has a bad equilibrium at $(0, 0, +\infty)$, which is stable if

$$\frac{\kappa(-\infty)}{\nu} - \delta < r \quad (3)$$

Examples

- Which species, in a mathematical model of interacting species, will survive over the long term?
- In a mathematical model of an epidemic, will the disease drive a host population to extinction or will the host persist?
- Can a disease remain endemic in a population?
- Reference: H. Smith and H. R. Thieme, *Dynamical Systems and Population Persistence*, Graduate Studies in Mathematics, 118. AMS, 2011.

Let $\Phi(t, x) : \mathbb{R}^+ \times X \rightarrow X$ be the semiflow generated by a differential system with initial values $x \in X$. For a nonnegative functional ρ from X to \mathbb{R}^+ , we say

- Φ is ρ -**strongly persistent** (SP) if $\liminf_{t \rightarrow \infty} \rho(\Phi(t, x)) > 0$ for any $x \in X$ with $\rho(x) > 0$.
- Φ is ρ -**weakly persistent** (WP) if $\limsup_{t \rightarrow \infty} \rho(\Phi(t, x)) > 0$ for any $x \in X$ with $\rho(x) > 0$.
- Φ is ρ -**uniformly strongly persistent** (USP) if $\liminf_{t \rightarrow \infty} \rho(\Phi(t, x)) > \varepsilon$ for any $x \in X$ with $\rho(x) > 0$.
- Φ is ρ -**uniformly weakly persistent** (UWP) if $\limsup_{t \rightarrow \infty} \rho(\Phi(t, x)) > \varepsilon$ for any $x \in X$ with $\rho(x) > 0$.

Example: Goodwin model

- (Goodwin 1967) Predator-prey system of wage share (ω) and employment rate (λ), with $\pi = 1 - \omega$:

$$\dot{\omega} = \omega[\Phi(\lambda) - \alpha]$$

$$\dot{\lambda} = \lambda[\pi/\nu - \alpha - \beta - \delta].$$

- This is e^π -SP and e^π -UWP, but not e^π -USP.

Modified Keen model with government

- Following Keen (and echoing Minsky) we model government spending and taxation as

$$\dot{G} = \Gamma(\lambda)Y$$

$$\dot{T} = \Theta(\pi)Y$$

and add government subsidies to firms as

$$\dot{G}_s = \Gamma_s(\lambda)G_s$$

- Defining $g = G/Y$, $g_s = G_s/Y$ and $\tau = T/Y$, the net profit share is now

$$\pi = 1 - \omega - rd + g_s - \tau,$$

and government debt evolves according to

$$\dot{B} = r_B B + G + G_s - T.$$

Denoting $\mu(\pi) = \kappa(\pi)/\nu - \delta$, a bit of algebra leads to the following seven-dimensional system:

$$\begin{aligned}
 \dot{\omega} &= \omega[\Phi(\lambda) - \alpha] \\
 \dot{\lambda} &= \lambda[\mu(\pi) - \alpha - \beta] \\
 \dot{d} &= \kappa(\pi) - \pi - d\mu(\pi) \\
 \dot{g} &= \Gamma(\lambda) - g\mu(\pi) \\
 \dot{g}_s &= g_s [\Gamma_s(\lambda) - \mu(\pi)] \\
 \dot{\tau} &= \Theta(\pi) - \tau\mu(\pi) \\
 \dot{b} &= b[r_B - \mu(\pi)] + g + g_s - \tau
 \end{aligned} \tag{4}$$

- Notice that π does not depend on b , so that the last equation in (4) can be solved separately.
- Observe further that we can write

$$\dot{\pi} = -\dot{\omega} - r\dot{d} + \dot{g}_s - \dot{\tau} \quad (5)$$

leading to the five-dimensional system

$$\begin{aligned} \dot{\omega} &= \omega [\Phi(\lambda) - \alpha], \\ \dot{\lambda} &= \lambda [\mu(\pi) - \alpha - \beta] \\ \dot{g}_s &= g_s [\Gamma_s(\lambda) - \mu(\pi)] \\ \dot{\pi} &= -\omega(\Phi(\lambda) - \alpha) - r(\kappa(\pi) - \pi) + (1 - \omega - \pi)\mu(\pi) \\ &\quad + \Gamma(\lambda) + g_s\Gamma_s(\lambda) - \Theta(\pi) \end{aligned} \quad (6)$$

- The system (6) has a good equilibrium at

$$\bar{w} = 1 - \bar{\pi} - r \frac{\nu(\alpha + \beta + \delta) - \bar{\pi}}{\alpha + \beta} - \frac{\Theta(\bar{\pi})}{\alpha + \beta}$$

$$\bar{\lambda} = \Phi^{-1}(\alpha)$$

$$\bar{\pi} = \kappa^{-1}(\nu(\alpha + \beta + \delta))$$

$$\bar{g}_s = 0$$

and this is locally stable for a large range of parameters.

- The other variables then converge exponentially fast to

$$\bar{d} = \frac{\nu(\alpha + \beta + \delta) - \bar{\pi}}{\alpha + \beta}$$

$$\bar{g} = \frac{\Gamma_b(\bar{\lambda})}{\alpha + \beta}$$

$$\bar{\tau} = \frac{\Theta(\bar{\pi})}{\alpha + \beta}$$

Bad equilibria - destabilizing a stable crisis

- Recall that $\pi = 1 - \omega - rd + g_s - \tau$.
- The system (6) has bad equilibria of the form

$$(\omega, \lambda, g_s, \pi) = (0, 0, 0, -\infty)$$

$$(\omega, \lambda, g_s, \pi) = (0, 0, \pm\infty, -\infty)$$

- If $g_s(0) > 0$, then any equilibria with $\pi \rightarrow -\infty$ is locally unstable provided $\Gamma_s(0) > r$.
- On the other hand, if $g_s(0) < 0$ (austerity), then these equilibria are all locally stable.

Proposition 1: Assume $g_s(0) > 0$, then the system (6) is e^π -UWP provided $\Gamma_s(0) > r$.

Proposition 2: Assume $g_s(0) > 0$, then the system (6) is λ -UWP if either of the following conditions is satisfied:

- ① $\Gamma_s(0) > \max\{r, \alpha + \beta\}$
- ② $r < \Gamma_s(0) \leq \alpha + \beta$ and
 $-r(\kappa(x) - x) + (1 - x)\mu(x) + \Gamma(0) - \Theta(x) > 0$ for
 $\mu(x) \in [\Gamma_s(0), \alpha + \beta]$.
