Tobin's
portfolio
selection in
macroeco-
nomics

M. R. Grasselli

Introduction

SFC models

The Ultimate
Model

Conclusions

- Tobin received the 1981 Nobel Memorial Prize “for his analysis of financial markets and their relations to expenditure decisions, employment, production and prices” .
- Well-known contributions included: foundations of modern portfolio theory (with Markowitz), in particular the Separation Theorem (1958), life-cycle model of consumption, Tobit estimator, Tobin's q , Tobin's tax, . . .
- Key forgotten contribution: financial intermediation, portfolio balances, flow of funds models and the credit channel.

Tobin 1969: A General Equilibrium Approach to Monetary Theory

- Specification of (i) a menu of assets, (ii) the factors that determine the demands and supplies of the various assets, and (iii) the manner in which asset prices and interest rates clear these interrelated markets.
- Spending decisions are independent from portfolio decisions.
- Each asset i has a rate of return r_i and each sector j has a net demand f_{ij} for asset i .
- Adding up constraint: for each rate of return r_k ,

$$\sum_{i=1}^n \frac{\partial f_{ij}}{\partial r_k} = 0.$$

- Paper proceeds to analyze several special cases: money-capital, money-treasuries-capital, bank deposits and loans.

Stock-Flow Consistent models

- Stock-flow consistent models emerged in the last decade as a common language for many heterodox schools of thought in economics.
- They consider both real and monetary factors simultaneously.
- Specify the balance sheet and transactions between sectors.
- Accommodate a number of behavioural assumptions in a way that is consistent with the underlying accounting structure.
- Reject silly (and mathematically unsound!) hypotheses such as the RARE individual (representative agent with rational expectations).
- See Godley and Lavoie (2007) for the full framework.

| Balance Sheet | Households | Firms | | Banks | Central Bank | Government | Sum |
|-----------------|----------------------|---------|------------|------------|--------------|------------|------|
| | | current | capital | | | | |
| Cash | $+H_h$ | | | $+H_b$ | $-H$ | | 0 |
| Deposits | $+M_h$ | | $+M_f$ | $-M$ | | | 0 |

| Capital | | | $+pI$ | pI |
| Sum | 0 | 0 | Π_u | pI |
| Change in Net Worth | 0 | $pI + \dot{p}K - p\delta K$ | $\dot{p}K + p\dot{K}$ | |

Table: SFC table for the Goodwin model.

- Define

$$\omega = \frac{w\ell}{pY} = \frac{w}{pa} \quad (\text{wage share})$$

$$\lambda = \frac{\ell}{N} = \frac{Y}{aN} \quad (\text{employment rate})$$

- It then follows that

$$\frac{\dot{\omega}}{\omega} = \frac{\dot{w}}{w} - \frac{\dot{p}}{p} - \frac{\dot{a}}{a} = \Phi(\lambda, i, i^e) - i - \alpha$$

$$\frac{\dot{\lambda}}{\lambda} = \frac{1 - \omega}{\nu} - \alpha - \beta - \delta$$

- In the original model, all quantities were real (i.e. divided by p), which is equivalent to setting $i = i^e = 0$.

| Change in Net Worth | S_h | | $(S_f + \dot{p}K - p\delta K)$ | | $\dot{p}K + p\dot{K}$ |

Table: SFC table for the Keen model.

- Assume now that new investment is given by

$$\dot{K} = \kappa(1 - \omega - rd)Y - \delta K$$

where $\kappa(\cdot)$ is a nonlinear increasing function of profits
 $\pi = 1 - \omega - rd$.

- This leads to external financing through debt evolving according to

$$\dot{D} = \kappa(1 - \omega - rd)Y - (1 - \omega - rd)Y$$

Denote the debt ratio in the economy by $d = D/Y$, the model can now be described by the following system

$$\begin{aligned} \dot{\omega} &= \omega [\Phi(\lambda) - \alpha] \\ \dot{\lambda} &= \lambda \left[\frac{\kappa(1 - \omega - rd)}{\nu} - \alpha - \beta - \delta \right] \\ \dot{d} &= d \left[r - \frac{\kappa(1 - \omega - rd)}{\nu} + \delta \right] + \kappa(1 - \omega - rd) - (1 - \omega) \end{aligned} \quad (1)$$

Introduction

SFC models

Goodwin model

Keen model

The Ultimate
Model

Conclusions

Figure: Grasselli and Costa Lima (2012)

- Costa Lima and Nguyen (2014) add random productivity to the Goodwin model and prove the existence of stochastic orbits for the generalized Lotka-Volterra system.
- Costa Lima, Grasselli, Wang and Wu (2014) show that government spending and taxation can prevent the bad equilibrium with infinite debt and zero employment.
- Choi and Grasselli (2014, in progress) characterize the Great Moderation in the U.S. as a Shilnikov bifurcation for the Keen model.

Shortcomings of Goodwin and Keen models

- No independent specification of consumption (and therefore savings) for households:

$$C = W, \quad S_h = 0 \quad (\text{Goodwin})$$

$$C = (1 - \kappa(\pi))Y, \quad S_h = \dot{D} = \Pi_u - I \quad (\text{Keen})$$

- Full capacity utilization.
- Everything that is produced is sold.
- No active market for equities.
- Skott (1989) uses prices as an accommodating variable in the short run.
- Chiarella, Flaschel and Franke (2005) propose a dynamics for inventory and expected sales.
- Grasselli and Nguyen (2014) provide a synthesis, including equities and Tobin's portfolio choices.

- Denoting demand by Y_d , expected sales by Y_e and capacity utilization by $u = Y/Y_{\max}$ we obtain the system

$$\begin{aligned} \dot{\omega}_e &= \omega_e [\Phi(\lambda) - \alpha + (1 - \eta_p)\gamma(1 - m\omega_e)] \\ \dot{\lambda} &= \lambda [g_e y_e + g_d y_d - \eta_v - \alpha - \beta] \\ \dot{d}_e &= d_e [-g_e y_e - g_d y_d + \eta_v + \gamma(1 - m\omega_e) + r] \\ &\quad + \left[\frac{\kappa(\pi_e) + \eta_u(u - \bar{u})}{u} - (1 - \omega_e)y_d \right], \\ \dot{y}_e &= y_e(\alpha + \beta - \eta_d - g_e y_e - g_d y_d + \eta_v) + \eta_d y_d \\ \dot{u} &= u \left[g_e y_e + g_d y_d - \eta_v - \frac{\kappa(\pi_e) + \eta_u(u - \bar{u})}{\nu} + \delta \right] \end{aligned}$$

of which the previous model is a special case.

- Suppose now that firms finance new investment by issuing equities E at price p_e as well as new loans.
- Assuming that undistributed profits take the form $s_f \Pi$ for a constant s_f , the amount needed to be raised externally for new investment is $pI_k - s_f \Pi$, according to the proportions

$$\begin{aligned}\dot{D} &= \nu_D [pI_k - s_f \Pi] \\ p_e \dot{E} &= \nu_E [pI_k - s_f \Pi],\end{aligned}$$

with $\nu_D + \nu_E = 1$.

- Here both I_k and ν_E can be functions of Tobin's $q = \frac{p_e E}{pK}$.

- On the other hand, the budget constraint for households is

$$W + (1 - s_f)\Pi + rD = pC + \dot{D} + p_e\dot{E},$$

whereas their portfolio allocation is

$$p_e E = f_e(r_e^e) X_h$$

$$D = 1 - f_e(r_e^e) X_h,$$

where

$$r_e^e = \frac{(1 - s_f)\Pi}{p_e E} + \pi_e^e$$

$$\dot{\pi}_e^e = \beta_{\pi_e} \left(\frac{\dot{p}_e}{p_e} - \pi_e^e \right)$$

- This leads to an extended system with two more equations for \dot{e}/e and $\dot{\pi}_e^e$.

Concluding remarks

- Macroeconomics is too important to be left to macroeconomists.
- Since Keynes's death it has developed in two radically different approaches:
 - ① The dominant one has the appearance of mathematical rigour (the SMD theorems notwithstanding), but is based on implausible assumptions, has poor fit to data in general, and is disastrously wrong during crises. Finance plays a negligible role
 - ② The heterodox approach is grounded in history and institutional understanding, takes empirical work much more seriously, but is generally averse to mathematics. Finance plays a major role.
- It's clear which approach should be embraced by mathematical finance.
