- Start when the economy is doing well but firms and banks are conservative.
- Most projects succeed - "Existing debt is easily validated: it pays to lever".
- Revised valuation of cash flows, exponential growth in credit, investment and asset prices.
- Highly liquid, low-yielding financial instruments are devalued, rise in corresponding interest rate.
- Beginning of "euphoric economy": increased debt to equity ratios, development of Ponzi financier.
- Viability of business activity is eventually compromised.
- Ponzi financiers have to sell assets, liquidity dries out, asset market is flooded.
- Euphoria becomes a panic.
- "Stability - or tranquility - in a world with a cyclical past and capitalist financial institutions is destabilizing".

Goodwin Model (1967) - Assumptions

- Assume that

$$N(t) = N_0 e^{\beta t} \quad (\text{total labour force})$$

$$a(t) = a_0 e^{\alpha t} \quad (\text{productivity per worker})$$

$$Y(t) = \nu K(t) = a(t)L(t) \quad (\text{total yearly output})$$

where K is the total stock of capital and L is the employed population.

- Assume further that

$$\dot{w} = \Phi(\lambda)w \quad (\text{Phillips curve})$$

$$\dot{K} = (Y - wL) - \delta K \quad (\text{Say's Law})$$

- Define

$$\omega = \frac{wL}{Y} = \frac{w}{a} \quad (\text{wage share})$$

$$\lambda = \frac{L}{N} = \frac{Y}{aN} \quad (\text{employment rate})$$

- It then follows that

$$\dot{\omega} = \omega(\Phi(\lambda) - \alpha)$$

$$\dot{\lambda} = \lambda \left(\frac{1 - \omega}{\nu} - \alpha - \beta - \delta \right)$$

- If we take Φ to be linear, this is a predator-prey model.
- To ensure $\lambda \in (0, 1)$ we assume instead that Φ is $C^1(0, 1)$ and satisfies

$$\Phi'(\lambda) > 0 \text{ on } (0, 1)$$

$$\Phi(0) < \alpha$$

$$\lim_{\lambda \rightarrow 1^-} \Phi(\lambda) = \infty.$$

- Then $(\bar{\omega}_0, \bar{\lambda}_0) = (0, 0)$ is a saddle point and the only other equilibrium

$$(\bar{\omega}_1, \bar{\lambda}_1) = (1 - \nu(\alpha + \beta + \delta), \Phi^{-1}(\alpha))$$

is non-hyperbolic.

- Moreover

$$g(\bar{\omega}_1) := \frac{\dot{Y}}{Y}(\bar{\omega}_1) = \frac{1 - \bar{\omega}_1}{\nu} - \delta = \alpha + \beta,$$

Introducing a financial sector (Keen 1995)

- Assume now that new investment is given by

$$\dot{K} = \kappa(1 - \omega - rd)Y - \delta K$$

where $\kappa(\cdot)$ is $C^1(-\infty, \infty)$ satisfying

$$\kappa'(\pi) > 0 \text{ on } (-\infty, \infty)$$

$$\lim_{\pi \rightarrow -\infty} \kappa(\pi) = \kappa_0 < \nu(\alpha + \beta + \delta) < \lim_{\pi \rightarrow +\infty} \kappa(\pi)$$

$$\lim_{\pi \rightarrow -\infty} \pi^2 \kappa'(\pi) = 0.$$

Accordingly, total output evolves as

$$\frac{\dot{Y}}{Y} = \frac{\kappa(1 - \omega - rd)}{\nu} - \delta := g(\omega, d)$$

- This leads to external financing through debt evolving according to

$$\dot{D} = \kappa(1 - \omega - rd)Y - (1 - \omega - rd)Y$$

Denote the debt ratio in the economy by $d = D/Y$, the model can now be described by the following system

$$\begin{aligned} \dot{\omega} &= \omega [\Phi(\lambda) - \alpha] \\ \dot{\lambda} &= \lambda \left[\frac{\kappa(1 - \omega - rd)}{\nu} - \alpha - \beta - \delta \right] \\ \dot{d} &= d \left[r - \frac{\kappa(1 - \omega - rd)}{\nu} + \delta \right] + \kappa(1 - \omega - rd) - (1 - \omega) \end{aligned} \quad (1)$$

- Define

$$\bar{\pi}_1 = \kappa^{-1}(\nu(\alpha + \beta + \delta))$$

- We verify that

$$\bar{w}_1 = 1 - \bar{\pi}_1 - r \frac{\nu(\alpha + \beta + \delta) - \bar{\pi}_1}{\alpha + \beta}$$

$$\bar{\lambda}_1 = \Phi^{-1}(\alpha)$$

$$\bar{d}_1 = \frac{\nu(\alpha + \beta + \delta) - \bar{\pi}_1}{\alpha + \beta}$$

is an equilibrium for (1) and satisfies the relation

$$1 - \bar{w}_1 - r\bar{d}_1 = \bar{\pi}_1$$

- Moreover

$$g(\bar{w}_1, \bar{d}_1) = \frac{\kappa(1 - \bar{w}_1 - r\bar{d}_1)}{\nu} - \delta = \alpha + \beta.$$

- If we rewrite the system with the change of variables $u = 1/d$, we obtain

$$\dot{\omega} = \omega [\Phi(\lambda) - \alpha]$$

$$\dot{\lambda} = \lambda \left[\frac{\kappa(1 - \omega - r/u)}{\nu} - \alpha - \beta - \delta \right] \quad (2)$$

$$\dot{u} = u \left[\frac{\kappa(1 - \omega - r/u)}{\nu} - r - \delta \right] - u^2 [\kappa(1 - \omega - r/u) - (1 - \omega)].$$

- We now see that $(0, 0, 0)$ is an equilibrium of (2) corresponding to the point

$$(\bar{\omega}_2, \bar{\lambda}_2, \bar{d}_2) = (0, 0, +\infty)$$

for the original system.

- Analyzing the Jacobian of (1) and (2) we obtain the following conclusions.
- The good equilibrium $(\bar{\omega}_1, \bar{\lambda}_1, \bar{d}_1)$ is stable if and only if

$$r \left[\frac{\kappa'(\bar{\pi}_1)}{\nu} (\bar{\pi}_1 - \kappa(\bar{\pi}_1) + \nu(\alpha + \beta)) - (\alpha + \beta) \right] > 0.$$

- The point $(0, 0, 0)$ is a stable equilibrium for (2) if and only if

$$\frac{\kappa_0}{\nu} - \delta < r.$$

To introduce the destabilizing effect of purely speculative investment, we consider a modified version of the previous model with

$$\begin{aligned}\dot{D} &= \kappa(1 - \omega - rd)Y - (1 - \omega - rd)Y + P \\ \dot{P} &= \Psi(g(\omega, d)P)\end{aligned}$$

where $\Psi(\cdot)$ is an increasing function of the growth rate of economic output

$$g = \frac{\kappa(1 - \omega - rd)}{\nu} - \delta.$$

With Ponzi financing the dynamical system becomes

$$\dot{\omega} = \omega [\Phi(\lambda) - \alpha]$$

$$\dot{\lambda} = \lambda \left[\frac{\kappa(1 - \omega - rd)}{\nu} - \alpha - \beta - \delta \right] \quad (3)$$

$$\dot{d} = d \left[r - \frac{\kappa(1 - \omega - rd)}{\nu} + \delta \right] + \kappa(1 - \omega - rd) - (1 - \omega) + p$$

$$\dot{p} = p \left[\Psi \left(\frac{\kappa(1 - \omega - rd)}{\nu} - \delta \right) - \frac{\kappa(1 - \omega - rd)}{\nu} + \delta \right]$$

- We find that $(\bar{\omega}_1, \bar{\lambda}_1, \bar{d}_1, 0)$ is a stable equilibrium iff

$$\Psi(\alpha + \beta) < \alpha + \beta.$$

- Introducing $u = 1/d$ we find that

$$(\bar{\omega}_2, \bar{\lambda}_2, \bar{d}_2, \bar{p}) = (0, 0, +\infty, 0)$$

is stable iff

$$\Psi(g_0) < g_0.$$

- Moreover, introducing $x = 1/p$ and $v = p/d$ we find that

$$(\bar{\omega}_3, \bar{\lambda}_3, \bar{d}_3, \bar{p}) = (0, 0, +\infty, +\infty)$$

is stable iff

$$g_0 < \Psi(g_0) < r.$$

- A final extension proposed by Keen (echoing Minsky) consists of adding government spending and taxation into the original system according to

$$\dot{G} = \Gamma(\lambda)Y$$

$$\dot{T} = \Theta(\pi)Y$$

- Defining $g = G/Y$ and $t = T/Y$, the net profit share is now

$$\pi = 1 - \omega - rd + g - t$$

- The new 5-dimensional system displays more local fluctuations, but no breakdown for the same initial conditions as before.

- Consider a stock price process of the form

$$\frac{dS_t}{S_t} = r_b dt + \sigma dW_t + \gamma \mu_t dt - \gamma dN^{(\mu_t)}$$

where N_t is a Cox process with stochastic intensity $\mu_t = M(p(t))$.

- The interest rate for private debt is modelled as $r_t = r_b + r_p(t)$ where

$$r_p(t) = \rho_1(S_t + \rho_2)^{\rho_3}$$

Stability map for $\omega_0 = 0.8$, $p_0 = 0.01$, $S_0 = 100$, $T = 500$, $dt = 0.005$, # of simulations = 100

- Introduce delay in the investment function
- Characterize the equilibria with government sector
- Study stochastic model analytically
- Model prices for capital goods P_k and commodities P_c explicitly (Kaleckian mark-up theory, inflation, etc)
- Calibrate to macroeconomic time series.

- Solow (1990): The true test of a simple model is whether it helps us to make sense of the world. Marx was, of course, dead wrong about this. We have changed the world in all sorts of ways, with mixed results; the point is to interpret it.
- Schumpeter (1939): Cycles are not, like tonsils, separable things that might be treated by themselves, but are, like the beat of the heart, of the essence of the organism that displays them.
